Executive Summary
India has done a remarkable job in terms of deployment of renewable energy-based installations, growing almost 3.5 folds in the last 5–6 years, with most of the capacity coming from onshore wind and solar photovoltaic (PV) based installations. At present India’s grid-connected solar PV sector is majorly dominated by the ground-based installations (93%) while the balance is contributed by rooftop the based solar PV installations. The installation cost of utility-scale solar PV in the country has declined by 84% between 2010-2018, making India world’s topmost country in achieving the lowest installation cost for utility-scale solar PV. It is well know that solar PV deployment is quite land intensive and scaling up the project sizes requires large chunk of contiguous land parcels, which becomes challenging in many situations. In order to keep pace of development commensurate with the national targets for solar capacity additions, alternatives are required to be explored and established. Floating solar PV (FSPV) or floatovoltaics is one such alternative, which has started getting traction worldwide and is expected to grow strongly over the coming years. It is estimated that the annual capacity addition may rise from the current installed of 1.314 GWp in 2018 to 4.6 GWp by 2022. Presently, China is the leading international market followed by Japan and South Korea. India also has very bright prospects to develop FSPV projects due to availability of large water bodies. As a technology, FSPV is in a very early stage of development in India. Till now, only a few projects with cumulative capacity of 2.7 MW have been installed. However, over 1.7 GW capacity projects are reported to be in various stages of development. FSPV market appears to inch forward to make its presence felt in India and the tariffs discovered through bids have already shown rapid reductions. So far large-to-medium size man-made inland waterbodies seems to have attracted initial interest to install FSPV based power plants, but all these waterbodies were created to serve various purposes like – irrigation, water supply, fishing, hydroelectric, navigation, etc., and this warrants great deal of diligence to balance out various usages of these waterbodies on the basis of accurate information.

The Energy and Resources Institute (TERI), New Delhi, India with support from the Energy Transitions Commission (ETC), India, has undertaken a study to analyse data on country’s medium and large reservoirs to estimate the potential of FSPV in the country. It is observed that about 18,000 km² water surface area spreading across various states and UTs is suitable for the installation of FSPV plants. The overall potential is a strong indication of the extent of the surface area than can be made available for setting up these projects, and even a capacity of about 280 GW is possible. The various factors determining the overall potential include percentage of water surface area coverage, water level variations, the purpose of the water body, and proposed plant location. The reports presents state-wise details of the potential in the form of a web-based user interactive tool – India Floating Solar PV-Tool. State-wise summary of FSPV potential along with the number of identified reservoirs and reservoir area is presented in Chart 1. The tool developed under this study also provides details regarding the historical changes in the waterbody, and is likely to be quite useful to stakeholder such as policy developers (viz. MNRE, NITI Aayog, state governments), projects developers, implementing agencies, investors, and financing institutions. The report also covers the best practice guidelines for installing FSPV projects.

Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?
1. Floating Solar PV – Understanding the Need
Why Floating Solar PV?

The total installed electricity generation capacity of the country has reached over 366 GW\(^3\). Out of which renewable energy share (RE) is 23.60% (84.4GW\(^4\)) and with recent cabinet approval of the addition of large hydro power plants (45 GW) as an RE source, the current share of RE in the total installation will become 35.18%. India has done a remarkable job in terms of deployment of RE-based installation, growing almost 3.5\(^5\) folds in the last 5-6 years, most of which have occurred in the onshore wind (37.27 GW) and solar PV (32.53 GW) sector. The majority of this growth in solar has been triggered by the launch of Jawaharlal Nehru National Solar Mission (JNNSM) on January 11, 2010. The target set under the mission was to achieve 20 GW of grid-connected solar power by the year 2022, which was later revised in the year 2015. The new targets under the mission are to achieve 175 GW RE capacities of which 100 GW is from solar by 2022. Out of this, 40 GW of the target is for installation of solar rooftop and 60 GW is for large-scale solar plants. To achieve its targets the Government of India has also taken various innovative policy measures such as viability gap funding (VGF), development of solar parks, and solar renewable purchase obligation (RPO), etc.

At present India's grid-connected solar PV sector is majorly dominated by the ground-based installations (93%\(^6\)) and rest is contributed by rooftop based solar PV installations. The installation cost of utility-scale solar PV in the country has declined by 84% between 2010-2018, making India the world's topmost country in achieving the lowest installation cost for utility-scale solar PV.

---

\(^3\) Central Electricity Authority (CEA). Details available at http://www.cea.nic.in/monthlyinstalledcapacity.html

However, the pace of utility scale solar PV deployment in the country has been reducing refer to Chart 2. Among several reasons, challenges related to the availability of land and, delay in land acquisition are considered as one of the key reasons behind this slow pace. Hence, in order to achieve the targets set under the JNNSM, it is a must to explore the other alternatives. Deployment of solar PV at distribution transformer (DT) level and floating solar PV (FSPV) are some of the alternative solutions that are emerging to boost solar installation. FSPV has an advantage in deploying solar PV as it is not dependent on land availability. There are more than 400,000 km² of the reported man-made reservoirs in the world⁷ out of which India has a share of about 70,000 km². This shows a vast potential that can be trapped for clean energy generation.

**What is Floating Solar PV?**

FSPV also known as floatovoltaics is a solar PV application in which PV panels are designed and installed to float on waterbodies such as reservoirs, hydroelectric dams, industrial ponds, water treatment ponds, mining ponds, lakes, and lagoons. In this, solar panels are usually mounted upon a pontoon-based floating structure and to keep its location fixed, floating structure is anchored and moored, (refer to Figure 1 for more details). Recently there has been an interest in FSPV globally as well as in India. Further, it is also seen that if the capacity of FSPV deployment is scaled up, the tariff may also come down closer to the tariff discovered for ground-mounted solar PV.

**Floating Solar PV – Benefit**

Some of the reported benefits of FSPV are as follows –

» **Higher gains in energy production:** Correlations between the solar PV array yield, solar PV array temperature, and local weather conditions such as ambient temperature, wind speed, solar irradiance, etc. are well known⁸,⁹. These correlations indicate that reduction in ambient temperature and higher wind speed reduces the solar PV array temperature which in turn results in higher energy yield. As the ambient temperature at the vicinity of a waterbody is generally lower than the ambient temperature at land and wind speed tends to be higher over open water surfaces as compared to on land, it resulting in an evaporative cooling effect. This effect results in lower operating temperatures of the PV cell, which in turn improves the energy yield. The improvement as much as by 10%

---

Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

as compared with land-based PV systems had been reported in a few studies\textsuperscript{10,11}. However, it is important to note here that this improvement in energy yield closely depends on the design of a floating platform, a gap between the water surface and the PV array, etc.

\textbf{Land neutral:} Since FSPV plants are installed on water surfaces, the land requirement is none or greatly reduced as compared to ground-mounted solar PV plants and hence FSPV is termed as land neutral. This is particularly of importance for developing countries like India, where land is scarce and land acquisition creates hurdles for deployment of solar PV projects.

\textbf{Reduction in water evaporation:} Loss of water resources due to evaporation is a well-known phenomenon, reported as high as 40%\textsuperscript{12} worldwide, and its effect is more significant particularly in dry and aired regions. As per an estimate by Central Water Commission (CWC) India, the evaporation loss in the country varies from 150-300\textsuperscript{13}cm per km$^2$ per annum. Since FSPV plants are deployed on the water surfaces, they provide shade to the water surfaces, thus reducing the amount of solar radiation reaching the water surface and also limiting the interaction of wind on the water surfaces. The combined benefit of these may results in reduction in the water evaporation losses\textsuperscript{14,15}. However, it is extremely difficult to exactly quantify the net effect on water evaporation loss due to deployment of FSPV plants since in general FSPV plants are installed on some fraction of a total water surface. Hence more studies are needed for quantification of this claim.

\textbf{Possibility of sharing existing electrical infrastructure:} Many inland waterbodies especially reservoirs used for various purposes like irrigation, water supply, reservoirs of hydroelectric plants, etc. have grid connections that are already available. Hence deploying FSPV plants in such cases may save investment cost by utilizing the already existing infrastructure.

\textbf{Complementary operation with hydroelectric power plants:} As of August 2019, India has 45 GW\textsuperscript{16} of installed capacity of hydroelectric power plants. Since most of these plants are seasonal, their output decreases particularly during dry seasons when water flow is less and solar radiations are high. Thus deploying FSPV plants in combination with already existing hydroelectric power plants would not only improve power production in lean seasons but also acts as energy storage, using solar power during the day and hydropower during the night. Since the response time of the hydro turbine is fast, the combination of hydroelectric–FSPV plant can be used for supplying power during peak demand.

However in some cases, hydroelectric plants having large variations in water level, pose difficulties in designing of anchoring and mooring for supporting the floating platform. Hence it is suggested to conduct a detailed study considering the effect of waterlevel variation on the viability of deploying the FSPV plants at any particular hydroelectric plant.

\textbf{Reduction in algae growth:} Among several other factors the growth in algae mainly depends upon

\begin{thebibliography}{9}
\bibitem{16} CEA monthly reports. Details available at - http://www.cea.nic.in/monthlyinstalledcapacity.html
\end{thebibliography}
light intensity and temperature of the water. Since FSPV plants provide shade to the water surface, they reduce the amount of sunlight reaching the water surface, which may cause a reduction in algae growth\(^\text{17}\). However, the effect of deploying the FSPV plants on the local water environment is still not well understood and would require further studies to understand the related issues.

» **FSPV as a new source of revenue:** Deploying FSPV plants can provide an additional source of revenue to a waterbody owner by—either utilizing the electricity generated via self-consuming, thereby reducing their own consumption or via selling the electricity generated to the grid. In either way, FSPV creates an economic value of a waterbody. For example, Jinko\(^\text{18}\) has installed 120-MW FSPV-based plant on a fishing farm at Poyang Lake in China, spread over 2000 acres of water surface and generating 137.70 GWh of electricity. Till now there are very few studies that provide some information on the potential impact of deploying FSPV on local ecology, hence it is suggested to conduct a detailed study before deploying large-scale FSPV plants.

» **Less soiling loss:** Since wind blowing over water surfaces contains less dust as compared to wind blow over land, FSPV plants are subjected to less dust as compared to land-mounted solar PV installations.

» **Ease of cleaning:** In case of FSPV plants deployed on inland waterbodies, water is readily available for cleaning purposes. However, the quality of the water needs to be checked and should be under the permissible limit as described by PV manufacturers.

» **Easy installation and deployment:** In general, installation of a typical FSPV plant is simpler and easy as compared to land-mounted solar PV plants. This is because of —(a) no civil work is required to prepare the site; (b) floating platform used to float solar PV arrays on a water surface are made in form of a modular individual floats which are prefabricated and are interconnected to form a large section, (c) floating platforms are assembled on land by adding rows of these modular interconnecting floats. Each of these rows is pushed into water as the next row being added to form a large platform. Once completed, the entire platform is towed to the exact location on the waterbody with the help of boats. As per discussions with India-based FSPV developer, the typical rate of FSPV plant installation, provided other supply chain is in place, varies from 2.5 kWp/person/h to 3.0 kWp/person/h.

However, FSPV has its fair share of challenges like higher capital costs, the potential for contamination of water, limited understanding of the technology, unavailability/limited knowhow of appropriate quality standards, technical specifications, etc. These issues are presented in detail in Chapter 7 of this report.

Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?
2. Global Market Overview
Global Scenario

In 2007, the National Institute of Advanced Industrial Science and Technology (AIST) built the world's first FSPV plant of 20-kWp capacity in Aichi, Japan. Later in 2008, the first commercial-scale installation of capacity 175 kWp came up at Far Niente Winery, California, USA. Most of these early projects are small-scale systems with a purpose of research and demonstration. From early 2013, megawatt scale FSPV plants started to appear in Japan and South Korea. Since then installations have increased many folds from few megawatt-peak (MWp) to more than 1300 MWp by the end of 2018.

The technology is currently deployed in more than 24 countries across the entire world with the majority of installations are coming up in Asia, particularly in Japan, China, and South Korea. The FSPV technology has been able to gather a lot of traction in the past 3 years (2016, 2017 and 2018) globally, which is evident from the increase in the installation presented in Chart 3. The total installed capacity now stands at 1314 MWp, which is further going to increase substantially in the years to come and expected to reach 4600 MWp by 2022, thanks to the recent increase in the activities in the sector in countries like China. Majority of installations till date are deployed on man-made waterbodies such as irrigation dams, industrial basins, water treatment plants, and unused mining ponds. More information on the current status of the FSPV projects in the top five countries is provided in detail in Chart 3.
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

Chart 3: Global installations of Floating Solar PV

Source: TERI's analysis based on a compilation of publicly available sources

*Excluding the UK
China is a leading country in terms of highest installation capacity accounting for more than 960 MWp out of global total of 1314 MWp. The country is also home to the world’s largest FSPV plant of 150 MW capacity installed at Huainan, south Anhui province. Most of the FSPV plants in China are installed at unused mining ponds. (refer Table 1 for more details)

![Chart 4: Project developers-wise installed capacity in China](image)

**Chart 4: Project developers-wise installed capacity in China**
*Source: TERI’s analysis based on a compilation of publicly available sources*

Japan

With more than 210 MWp of installed capacity, Japan is a leading country in terms of total numbers of installation and home to 73 of the world’s 100 largest FSPV plants. The majority of these plants are installed on man-made waterbodies having main purpose to retain rainwater or irrigation. (refer Table 1 for more details)

![Chart 5: Project developers-wise installed capacity in Japan](image)

**Chart 5: Project developers-wise installed capacity in Japan**
*Source: TERI’s analysis based on a compilation of publicly available sources*

The Republic of Korea

Korea was among the early mover to have adopted FSPV. Till date the country has installed more than 79 MWp of FSPV plants and more than 2300 MWp are in pipeline. Korea was the first country to install a tracking-based FSPV plant having a capacity of 465 kW in 2014. Recently, the Ministry of Trade, Industry, and Energy (MOTIE) has announced its plans for developing 2.1 GW of FSPV-based projects at Saemangeum Seawall Dyke located on the southwest coast of the country. The project will be built in two stages. The first stage with a capacity of 1.2 GW is to be completed by 2022 and the remaining 900 MW by 2025 in the second stage. Upon completion, the project will be 14 times larger than the present world’s largest 150-MW FSPV-based project of China.

![Chart 6: Project developers-wise installed capacity in the Republic of Korea](image)

**Chart 6: Project developers-wise installed capacity in the Republic of Korea**
*Source: TERI’s analysis based on a compilation of publicly available sources*

Taiwan, China

With more than 26 MWp of installed capacity and more than 180 MWp in pipeline, Taiwan is among the fastest-growing FSPV markets and the fourth largest country in the world in terms of total installed capacity. The majority of these plants are installed on water retention reservoirs and irrigation dams (Refer Table 1 for more details). The country’s largest FSPV plant of 9.9MW capacity is installed at the Agongdian reservoir covering 9.19 hectares of water surface area.

![Chart 7: Project developers-wise installed capacity in Taiwan, China](image)

**Chart 7: Project developers-wise installed capacity in Taiwan, China**
*Source: TERI’s analysis based on a compilation of publicly available sources*
The UK

With more than 13 MWp of installed capacity, the UK is the fifth largest country in terms of FSPV installation. Like many other Asian countries, lack of space for land-mounted PV in the country is the main reason for going towards FSPV plants. The majority of the plants in the UK are installed on irrigation and water treatment ponds. In March 2016, the world’s first deep water reservoir (maximum depth of 18.4 m) based FSPV plant of 6.4 MWp was installed at the Queen Elizabeth II reservoir in the UK.

Source: TERI's analysis based on a compilation of publicly available sources
The FSPV as a technology is still in the nascent stages of development in India. The journey started with a 10kW FSPV plant on a pond in Rajarhat, Kolkata in 2015. The project was part of a research activity sponsored by the Ministry of New and Renewable Energy (MNRE). In 2016, NTPC installed country’s largest 100kW plant on a reservoir of its combined cycle power plant situated in Kerala’s Kayamkulam district. Later in December same year, Kerala State Electricity Board started its operation of 500kW plant at Banasura Sagar reservoir in Wayanad district replacing NTPC’s 100kW as a largest FSPV-based plant. The plant is actually a scaled-up version of the 10kW plant commissioned in January 2016 at the same location. The plant was able to bring some confidence to FSPV promoters by successfully surviving the recent flood ravage in the state. The recently commissioned 2MW project at Visakhapatnam, Andhra Pradesh has now the largest FSPV-based plant commissioned in the country till date and with this the total installed capacity of FSPV has becomes 2.7 MW. The FSPV sector is now getting a lot of attention in the country, which can be seen via an increase in the numbers of tenders that are released in the past 2 years. At the moment there is more than 1700 MW worth of projects, which are in various stages of development and more are in pipeline making the outlook very positive for this new segment.

**Cost of Floating Solar PV Plants**

This section describes the investment cost trends of the recent FSPV projects, which are purely based on the publicly available data. Since FSPV technology has just started getting tractions, accurate data related to project capital and operating cost are not disclosed in the public domain. Hence it is suggested to take the data presented as indicative and not as a generalized cost for the technology. Also at present, as there are a few projects that are installed and are in operation, it is very difficult to calculate their operations and maintenance cost. Thus only capital costs are used to showcase the investment cost trends in Chart 10. This is important to note that some amount of approximations is applied on the publicly available data.

1 MWp of FSPV plant would generate 1.5–1.65 million units under typical conditions in India
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

It is interesting to see how the cost had decreased in the past 2 years. Especially the country like India has already started getting the lowest cost in the world and one can expect it to go down further, as more projects are about to come in the near future. More details on cost trends in India are presented in Chart 11.

**Chart 10**: Global investment cost for floating solar PV plants  
*Source: TERI’s analysis-based on a compilation of publicly available data*

**Chart 11**: Investment cost for floating solar PV projects in India  
*Source: TERI’s analysis-based on a compilation of publicly available data*
Recent bids results indicate a sharp decline in the investment cost for FSPV. In the latest tender result of the country’s first large-scale FSPV plant of 70MW capacity, cost as low as INR 35 per Wp has been quoted by developers. This is the lowest cost achieved in the entire world so far. Further considering last year’s trends, one can see the 45% reduction in the cost, which is significant. Even though the costs have decreased, it is still very early to come to any generalization, since the FSPV as a technology is still in its early stage of market penetration. The reduction in costs, particularly in India may be linked to many factors like – decrease in the cost of floaters because of improvement in manufacturing process, reduction in the material cost, reduction in thickness of floaters, aggressive biddings by project developers to get some experience in FSPV sector seeing the high growth in national as well international markets etc. However, it is very early to arrive at any conclusion. While falling cost is a welcome trend, it is also important to check whether this is not impacting the overall quality of the projects, since degradation in the quality of FSPV projects has higher potential to impact local biodiversity compared to ground-mounted solar PV. Hence it is essential to form proper guidelines/standards to keep the things in check from the initial stage of market development of FSPV technology.

In general, the cost for setting megawatt scale FSPV plants depends upon the following:

- Project location
- Depth of waterbody
- Waterlevel variation
- Site conditions – wind speed and its direction, solar irradiations, ambient temperature, humidity levels, etc.
- Size of the plant

Chart 12 presents component-wise cost breakup share of a typical megawatt scale FSPV-based project. Just like ground-mounted solar PV plants, the PV module has a major share in overall cost breakup. The main difference lies in the cost of the floating platform and anchoring and mooring system, representing approximately 38% of overall cost.

**Supporting Frameworks for FSPV**

The FSPV sector is becoming popular day by day but still, there are very few countries that are providing any kind of support/incentives exclusively for FSPV. Unlike ground-mounted solar PV, there are no specific standards or policy for FSPV technology as of now. A few Asian countries like Japan, Malaysia, Vietnam, etc., are following preferential feed-in tariffs for FSPV. Till now most of the FSPV projects in these countries are small in size (less than 5 MW) and financed by local/national banks in local currencies. However, large international commercial banks as well as multilateral developments banks which were only supporting small-scale studies, now moving towards financing FSPV projects resulting in the development of large-scale projects. In general, in some countries like China,
Japan, Korea, and India existing initiatives like RE targets set under the national policies are driving the demand for development of the new projects (size >2–5 MW) while in some other countries financial support is provided for pilot-scale demonstration projects. For projects having size > 2-5 MW, tenders and auctions are the chief ways which are being used to implement FSPV projects. The analysis of policy and other supporting frameworks are discussed as below:

**China**

Presently, China is a leading country in terms of total installed capacity in FSPV and accounting for 73% of global installations. The majority of these projects are installed on flooded mines and having a capacity of greater than 5 MW. Most of these large-scale FSPV projects in China are developed under the country’s Top Runner Programme, which is targeting 201–270 GWp solar PV installations by the year 2020.

**Japan**

As highlighted in this report, Japan is the second-largest country accounting for 16% of the total global installations of FSPV. Japan developed the world’s first floating pilot project of 20 kWp in 2007. Mostly all solar projects in Japan have been implemented based on preferential feed-in tariffs (FiTs). But 2017 onwards FiTs benefits are not applicable to larger projects (≥2 MWp) and electricity tariff is now calculated by competitive bidding process.

**Taiwan, China –**

With over 26 MWp of installed capacity and more than 180 MWp worth projects are in various stages of development, Taiwan, China is the fourth largest country in the world. It is among the few countries that are offering a specific FiTs to FSPV projects. As per the Ministry of Economic Affairs, FiTs for FSPV projects in the first half of 2019 vary from NT$4.5016/kWh (for an off-grid project) to NT$4.345/kWh (for grid-connected projects), about 10% higher than the land-based solar PV of the same size.

**The Republic of Korea**

The Republic of Korea has set an ambitious target of achieving 30.8 GW of installed capacity by 2030 from solar and 35% of energy generation from RE-based sources by 2040. In order to accelerate the country’s RE deployment and to create a competitive market environment, in 2012 FiTs was replaced by Renewable Portfolio Standard with an aim to steadily increase RE mix in the total power generation in the period 2012–2024. Under this, power producers having installed capacity greater than 500 MW are required to generate minimum percentage (also know as obligatory renewable service supply ratio) of generation from a new and renewable energy source. Based on the energy generated from RE sources, Renewable Energy Certificates (RECs) are provided to power generators. These RECs are calculated based on the weighing scheme under which weights are applied to various RE sources. A weightage of 1.5 is applied to FSPV as compared to 0.7 for land-based solar PV.

**India**

As highlighted in this report, until now the cumulative installed capacity of FSPV-based projects has reached to 2.7 MW. However, it is going to increase many folds by the end of 2019, as projects 1721 MW are in the various stages of development at the moment. The majority of these projects are developed through a tendering process. The Solar Energy Corporation of India (SECI) is the leading organization followed by NTPC Ltd, NHPC, state-level distribution companies (like Kerala State Electricity Board Limited), and city development authorities such as the Greater Visakhapatnam Smart City Corporation Limited (GVSCCL), etc.

**The Netherlands**

In 2017, the Ministry of Infrastructure and Water Management, Netherlands had created a consortium called ‘Zon op Water’ to develop 2 GWp of FSPV by 2023. The consortium aims to install many demonstrations of FSPV projects. Under the government subsidies scheme of SDE+, 1.8MWp FSPV plant at Gelderland was financed through a non-recourse loan from ING.

**The USA**

In some places in the USA, like Massachusetts, special compensation rates (location based) for FSPV projects are given. In 2018, Solar Massachusetts Renewable Target (SMART) programme was launched, which offers compensation rate add-on of $0.03/kWh for FSPV projects.
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?
3. Floating Solar PV as Technology Overview
FSPV design is similar to a conventional solar PV system except it requires a special arrangement to float on the water surface. The typical floating structure supports the PV arrays, inverters, combiner boxes, lighting arresters, etc. on a floating bed, which is made of fiber-reinforced plastic (FRP) or high-density poly ethylene (HDPE) or metal structures. The whole floating bed is buoyed with the help of anchoring and mooring systems. The detailed description of floating solar components is given below:

**PV Modules**

The basic integral part of the FSPV plant is solar PV modules and like conventional solar projects generally, poly or monocrystalline or thin film solar panels are used for the installation of the project. Selection of PV modules technology also defers because of space, cost, relative humidity, type of water-bodies, etc. The criteria for selection of PV modules are as follows:

- Solar panel performance – power tolerance, efficiency, temperature coefficient especially in high moisture, and high humidity conditions

**Inverters**

Like a conventional solar plant, DC power generated from solar PV modules is taken to the inverter through a series of combiner boxes and finally converted into AC power. A developer may select multiple string inverters or central inverters.

Depending upon scale and distance from shore, inverters can be placed either on a separate floating platform or on land. Generally, for smaller capacity FSPV inverter may be located on land near to PV arrays, otherwise for large
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

capacity plants it is advisable to place inverter on a floating platform to avoid excessive resistive losses. Both the types have some inherited advantages and disadvantage and choosing one over another must be done wisely.

**Floating Platform**

This is the most crucial component of FSPV; it supports all necessary components like solar PV during the project time. Hence selection of appropriate materials for the floating platform becomes imperative. HDPE is the most popular material being used in a majority of the FSPV power plants across the globe. Other materials like FRP, medium density polyethylene (MDPE), and ferro-cement are also been utilized as materials for the floating platform. Various designs of a floating platform are described below.

**Pure-floats design**

It uses a specially designed float that can hold PV panels directly. The entire system is made in a modular fashion and has a provision to join with pins or bolts to make a large platform. Every single unit of such a system typically consists of the main and secondary floats. The main purpose of the secondary float is to provide a walkway for maintenance and additional buoyancy. The design is being used by a few manufacturers, some of them are as follows:

» Hydrelio from Ciel & Terre

The Ciel & Terre is a French technology provider, providing innovative floating solar solutions since 2011. In fact, it has the majority of market share in terms of total numbers of installations across 25

---

**Figure 3:** (A) Central inverter placed on floating platform at China. (B) String inverter

*Source: Sungrow*

---

**Figure 4:** Hydrelio design

*Source: Ciel & Terre*
countries, accounting for more than 300 MWp of installed capacity. Hydrelio floats are made of HDPE and connection pins are made of polypropylene combined with fiberglass. The floats are manufactured by blow molding and pins are made from injection molding.

» Sumitomo Mitsui Construction Co. Ltd.
The design is conceptually similar to Ciel & Terre, with some additional features like more regularly shaped float for denser packing and easy transportation. Additionally, a float is filled with polystyrene foam reducing the risk of sinking even when damaged and there is a usage of binding bands in the connecting part, which reduces the risk of structural failure for floats.

» Yellow Tropus Pvt Ltd.
The Yellow Tropus is an India-based design and engineering company focused and specialized in the development of FSPV power plants. The company is offering three types of technology for land-neutral FSPV plants which are as follows:
- Seahorse technology – One single unit of this consists of one walkway float and two solar PV panel float for supporting two solar PV panels.

![Figure 5: Floating platform](image)
*Source: Sumitomo Mitsui Construction Co. Ltd*

![Figure 6: Seahorse technology](image)
*Source: Yellow Tropus Pvt Ltd*
• Stingray Technology – It aims to minimize losses due to evaporation by covering more fraction of water surfaces. As per the company’s claims the technology is best suitable for large waterbodies that include thermal power plants, steel plants, chemical industries, water tanks that is manmade waterbodies with no aquatic life. One unit of this supports three solar PV panels and has two float sections namely South C-Hex float and North C-Hex float.

Figure 7: Stingray technology
Source: Yellow Tropus Pvt Ltd

**Pontoon + metal structures design**

The other common design which is used by some project developers uses a metal structure similar to land-based system and pontoons to provide buoyancy, hence eliminating the need for specially designed floats. The main advantage of this type of design is, easier to make floats and hence can be manufactured locally. However, access for operation and maintenance is difficult in such designs.

Figure 8: Floaters design

**Anchoring and Mooring System**

Since FSPV plants are installed on water bodies, any variations in water levels induced by monsoon, wind velocity or increase/decrease in water quantity could be problematic for the plants. To avoid this situation, FSPV plants are anchored through mooring systems. The placement of a mooring system must take into account the location, bathymetry, soil conditions, and water-level variations. Mooring systems include quays, wharfs, jetties, piers, anchor buoys, and mooring buoys. Mooring system for a floating platform is generally attached with nylon polyester or nylon nautical ropes that are further tied to bollards on the bank and lashed at each corner. Mooring can be done in the following three ways – bank anchoring, bottom anchoring, and piles.

» Bank anchoring – This type of anchoring is particularly suitable for sites, which are shallow, small and where the bottom of the water basin does not allow any kind of anchoring. Bank anchoring is the most cost-effective option and its suitability depends on the conditions of the shore. The main disadvantage of this type of mooring is its visibility from outside, impacting the landscape view.

» Bottom anchoring – Due to its suitability and flexibility, this type of anchoring is more popular than other
types. This can be done in two ways – inserting anchors directly into the bottom of the waterbody and anchoring through concrete block placed at the bottom of the waterbody. The anchors are then connected to a floating platform with the help of mooring cable and chain. The cost of bottom anchoring is generally higher than other types as it requires careful planning while designing and involves divers.

- **Piles** – In this, piles are drilled into the bottom of the waterbody and the floating platform then be moored to the piles. The main advantage of this type of configuration is in their capability to handle water level variations however, the need for heavy equipment and civil work makes it expensive.

### Cabling

In case of FSPV plants, cable routing and its management requires cautious planning. Unlike ground-based solar PV installations, movement of floating platform on a water surface causes cable length to vary in FSPV plants. The movement of floating platform is due to wind load and variations in water level. This requires extra length in form of slack to be provided for accommodating the movement of the floating platform. Neglecting this, insufficient cable length may result in cables to snap and rupture due to the tension. Apart from the cable length the other parameters upon which cable size depends are voltage and current of the cable and losses from the cable.

The cables can be routed in two ways – either via float on water surfaces or via submarine cables, later one being costlier. Cable trays, cable conduits, and cable clip holders are used to keep cables on the water surface. Cables used must be UV-resistant, and uses of wiring trunks are recommended to protect them from direct sunlight. To avoid DC cables/ conduits coming into contact with water, it is recommended to use proper cable ties or clamps. Similarly AC cables can be routed either via separate dedicated floats or via use of submarine cables for the connection to main electrical infrastructure onshore. In a nutshell the following element play vital role while sizing the cable and its routing in case of FSPV plants:

- Plot size
- Distance to shore
- Placement on inverters, transformers
- Quality of water
- Variations in water level

### Unconventional Concepts in FSPV

#### Tracking

Like the ground-mounted solar PV panels, floating platforms can also be designed in a way to track the sun in single as well as dual axis, later being slightly difficult to achieve in the of FSPV. Tracking in a single axis (vertical-axis azimuth tracking) is relatively simple as low resistance is offered by water layer as compared to on land. In some of the initial designs of this type, platform (usually of circular shape) is moored around a central pile and motors are used to rotate it around a vertical axis of the central pile, thereby enabling

![Figure 10: A–200 kWp grid-connected single axis based floating solar PV plant in Suvereto, Italy](Source: Koine' Multimedia)
single-axis rotation to track the sun in single axis. In some other designs, central pile is replaced by a fixed outer ring, which surrounds the floating platform.

In a recent development, India-based Yellow Tropus Pvt Ltd claims the world’s first dual-axis-tracking (DAT) FSPV plant technology capable of generating 40% higher energy generation as compared to land-based solar power plants. A typical plant based on this technology consists of a toroidal wave attenuator, a Y-shaped flotation device resembling a hexagonal honeycomb shape grid after assembling, and a tracking system to track the sun in the two axes. The main function of toroidal wave attenuator is to balance out the effect of turbulence caused by high winds and waves, hence acting as the first line of defense and providing guidance for azimuthal tracking.

**Concentrated FSPV**

As the name depicted, this uses a reflecting mirror or Fresnel lens to concentrate the sun rays on the solar PV cell/panel. In principle, the technology is similar to ground-mounted concentrated solar PV (CSPV), the only difference is an assembly of solar PV cell/panel and reflecting mirror/concentrating lens is mounted on the floating platform instead of attached to the ground. Readily availability of water as a coolant and lower ambient temperature could make this technology more relevant as compared to the...
ground-mounted one. However, the constant movement of a floating platform on a water surface makes it difficult to track the sun along the two axes, resulting in lower concentration ratio.

In another design of its kind in India, a pilot project uses a concentrator made out of plastic also known as liquid solar array (LSA). The lightweight plastic lens rotates to track the sun to achieve the required rotation needed. The PV cells are placed beneath the concentrator in a PV container that sits in the water. This helps in dissipating heat generated due to high concentration and keeping the PV cells cool. The key feature of this technology is its simplicity and minimal use of materials.

Membranes and mats type

In this type of platform, rubber mats are generally used to entirely cover the water surface. These rubber mats now act as a base for solar panel installation. This type is particularly suitable for small manmade waterbodies (size less than 0.2 km²), which are primarily used for water storage and have no aquatic life. Some advantages of this type of platform are simplicity in design, easy installation, and maintenance, the ability to accommodate changes in the level of water, etc. The type is especially suitable for areas prone to water scarcity like a desert and arid areas.

In another design by the company name Ocean Sun from Norway, a floating platform is made of rafts, which is 70 m long.
in diameter. Each raft is like a giant inflatable pool made of a plastic ring and a thin membrane.

Submerged FSPV

As the name indicates, in this type PV modules are directly placed just beneath the water surface. Apart from achieving the lower module temperatures, one major advantage of this type is its simple mooring requirement due to reducing mechanical loading and lesser internal stress because of the use of flexible modules as compared to conventional PV modules with rigid mounting structure. An increase in the flexibility of the entire system reduces the number of material requirements and also makes transportation easy. However, the technology is in its nascent stage at the moment and has some concerns like long-term reliability of PV modules and electrical safety under submersible conditions. MIRARCO mining innovation had deployed the world’s first test system having 0.57 kWp capacity in 2010.
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?
4. Floating Solar PV – India Potential
India is known to have a large number of man-made reservoirs, which are used for a variety of purposes like irrigation, hydroelectric, water supply, navigation, etc. In fact, as on June 2019, share of installed hydroelectric capacity stands at 45 GW out of 366 GW of total installed capacity of the country, representing 12.8% share in the total. These reservoirs impound large volumes of water during monsoon for eventual use during lean season. The prevalent high temperatures and arid conditions, however, result in substantial evaporation losses from these reservoirs. CWC estimates that average annual evaporation from reservoirs/waterbodies in India varies from 1.5 m to 3.0 m per km². Thus FSPV presents a possibility to generate clean energy via a technology that is land neutral and has the potential to conserve water by reducing the evaporation losses.

Potential Assessment Tool

Chart 13 presents the steps that were carried out for assessing the FSPV technology’s potential for the country. Due to the unavailability of any single point data source, data from several open-source databases like CWC, WRIS, state water resources department, Indian Meteorological Department (IMD), NREL, etc. were gathered. The data collected were cleaned and arranged in a uniform format for further analysis. Each data point was then geo-referenced to find out the information like latitude and longitude. Duplicate data points were removed in the next steps and additional information like the nearest city, states, purpose, solar radiation, monthly average ambient temperature, reservoir surface area, water depth, reservoir age, etc. were added to each data points. Reservoirs with water depth lesser than 2 m and surface area lesser than 4,000 m² were filtered out from the database. Even though only man-made reservoirs were included for assessing the potential of FSPV, covering 100% of the surface area was not feasible due to – (a) most of the reservoirs are more than 20 years old and they may have developed some type of aquatic life during this period. Hence covering 100% of the water surface may have a negative impact on aquatic life and local biodiversity. (b) These reservoirs have also been used for other purposes like irrigation, water supply, navigation, recreational activities, fishing, etc. Thus covering 100% of the surface area is not feasible. (c) Some of the reservoirs are spread across very large areas making it practically unrealistic. Hence a range of percentages was assigned to calculate the useable area, which was further used to calculate the potential. The range is set based on the purpose of the reservoir. For example, for a reservoir with a purpose of irrigation, FSPV plant can be installed on 5%–30% of its surface area, for reservoir with a purpose of generation of electricity, FSPV plant can be installed on 5%–10% and so on.

Table 2 provides the range of percentage considered for each purpose type. Once the usable area is known, its value is then used to calculate the potential. Further, historical changes in the water surface of each data point was then accounted for.

---

20 As per the Ministry of Water Resources (MOWR) ‘reservoirs’ defined as - “A large man-made impoundment of varying magnitude created by erecting, bunds, dams, barrages or other hydraulic structures across streams or rivers serving one or more purposes such as irrigation, power generation, flood control or other water resource development projects”

21 Central Electricity Authority (CEA). Details available at -http://www.cea.nic.in/monthlyinstalledcapacity.html

Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

Point were analysed by using the open-source database of Landsat satellite imagery. The methodology of using these data sets is described in detail by Pekel, Andrew, Cottam et al. Based on this, permanently dried data points were removed and reservoir area value of the remaining data points was adjusted. Google maps were used for removing the reservoirs located in the protected areas like – wildlife sanctuaries, protected forest areas, etc. Two scenarios as presented in TERI’s Analysis.

Table 2 were used for calculating the potential of each data point. Finally, a web-based user interactive tool was developed (see Chart 14). The tool highlights the prospective FSPV locations, spreading across the country. Size of the bubble depicts the size of the FSPV plant which can be installed on that particular location.

Lastly, state-wise potential numbers were populated. Refer Chart 15 for more details on the state-wise potential for FSPV along with the total number of reservoirs on which FSPV can be installed along with cumulative reservoir area.

---

Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

**Chart 15:** State wise estimated potential of FSPV

*Source: TERI analysis*
As indicated above, all the identified reservoirs are attributed with parameters such as—solar radiation, reservoir depth, waterlevel variation, reservoir age, and infrastructure, availability such as site accessibility, vicinity to transmission infrastructures, etc. These parameters play vital role in choosing any particular site for installation of FSPV-based plants. For example, the cost of anchoring and mooring highly depends on the depth\(^2\) of the water body on which FSPV plant is installed, therefore, reservoirs with lower depth (<30 m) are generally preferred over the reservoirs with higher depth (>30 m). Thus it is important to identify such reservoirs. All identified reservoirs are further categorized into the following five distinct reservoir depth classes:

- **VHD** – Very High Depth (depth ≥ 100 m)
- **HD** – High Depth (30 m ≤ depth < 100 m)
- **MD** – Medium Depth (15 m ≤ depth < 30 m)
- **LD** – Low Depth (10 m ≤ depth < 15 m)
- **VLD** – Very Low depth (3 m ≤ depth < 10 m)

Similarly, reservoir's age is also an important parameter, which provides some indication on a reservoir’s capability to hold FSPV plant over its entire life. To include the effect of this, all identified reservoirs were further categorized into the five distinct categories of reservoir age: >200 years old, 100–200 years old, 50–100 years old, 20–50 years old and 0–20 years old.

### Setting Priorities

As presented in this study earlier, even though numbers presented in Chart 15 showcase huge potential of FSPV in the country there is a very limited amount of data available at the moment, raising speculations on the long-term viability of this new technology. Hence in order to reap the benefit of this technology, it is essential to create local knowhow via concentrating more on the long-term impact of technology through proper monitoring of projects. Learning through these initial projects would then be utilized in setting standards and guidelines for further developing such projects. Based on the data gathered, the study tries to identify the difficulty levels in setting up the FSPV-based projects for all the locations and rank them in form of priority, that is, Priority I, Priority II, and Priority III. Locations involved under Priority I are the ones that are considered as ‘low-hanging fruit,’ requiring minimum level of knowhow (which is equivalent to the current technical knowhow for FSPV in the market) available presently and thus easy to install. Refer Chart 16 for more details on the priority-wise potential.

---

\(^2\) Cost of anchoring and mooring depends on the lowest depth of waterbody and waterlevel variation. Hence it is suggested to consider effects of both of these parameters while choosing any particular location for installation of FSPV plants. Variation in water level in any waterbody is a local phenomenon and it depends on the waterbody usage, seasonal behaviour of water body (variation in rainy and dry seasons) and connectivity to other waterbody. Since aim of this study is to present the state-wise high level (realistic) preliminary estimation of the FSPV potential for the entire country, effect due to waterlevel variations are not considered while estimating the potential.
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

**Chart 16:** Priority-wise Floating Solar PV potential – Priority I, Priority II, and Priority III

*Source: TERI’s analysis*
5. Floating Solar PV – Potential Environment and Social Impact
FSPV plants are often installed on in-land bodies of water and these waterbodies are used for a variety of purposes such as drinking water, irrigation, recreation, generation of electricity, etc. Frequently these waterbodies are also tagged as ‘lifeline’, deploying large-scale FSPV plants might have a notable impact on the social development of mankind. Figure 19 tries to depict some of the potential impacts of deploying large-scale FSPV.

A few of these potential impacts of deploying large-scale FSPV plants are due to the following:

» Impact on local marine aquaculture due to the reduction in sunlight reaching the water surface
» Impact on the fishing pattern
» Impacts of shading of water surface on temperature stratification and dissolved oxygen levels
» Impact on water quality

Inhibits the breakdown of chemicals by prompting high dissolved organic carbon concentrations potentially increasing the costs of water treatment

Impact due to leaching from materials

Impact due to exposure to electromagnetic fields associated with underwater electrical cables

Impact on hunting grounds of surface-diving birds

Impact on migratory birds habitats

Till now there are very limited data available and the long term effects of deploying large-scale FSPV on waterbodies are poorly understood. Also, it is important to note that since waterbody characteristics vary widely, the scale of impact is site-specific in nature and hence it is vital to take all factors into consideration before deploying FSPV plants at large scale for each site.

Figure 19: Potential impact of deploying large-scale floating solar PV

6. Floating Solar PV – Project Design Guidelines
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?

FSPV as a technology is still in the developing phase and there are several vital elements including methods/steps for establishing FSPV plants that are not available publicly. Hence, developing the best practice guidelines for FSPV sector would help project developers, investors, and policymakers in understanding the procedures of FSPV project development. In a nutshell, major steps of developing an FSPV project can be understood through Chart 17.

**Chart 17:** A flow chart of floating solar PV project design

*Source: TERI’s analysis*
**Initial Site Assessments**

The initial site assessments of the proposed waterbody should be carried out to understand the feasibility of the site for the FSPV project development. The site assessments can be executed in the two following steps:

- **GIS-based assessment** – Assessments through the GIS tool really help in finding out the site feasibility for an FSPV plant establishment. The GIS tool provides information on water surface variations due to seasonal changes in the past years. The outcome of the analysis gives an approximate surface area of the waterbody which remains permanent irrespective of seasonal water-level deviations.

- **Field assessment** – An initial site visit is essential to understand the ground reality of the site conditions. The visit mainly covers the assessment of type of waterbody and its purpose, accessibility to the site, location of nearest substations, and information on restricted area. In case the waterbody is used for some industrial purposes or in power plants or water treatment plants, etc., details like fire hazard buffer zone, nearby building infrastructure for calculating the shadow-free area, availability of space while installation, space available near shore while placing the floating platform into waterbody, etc., are some of the important points that need to be looked into.

Eventually, the initial site assessments assist in estimating a suitable area for FSPV installation and water quality of reservoir/pond/lagoon.

**Bathymetry/Hydrography and Soil Testing**

A bathymetric survey is a method to estimate the depth of a waterbody, and it also helps in understanding the underwater geography of a particular waterbody. There are several methods available for carrying out bathymetric surveys such as multibeam, single beam, sub-bottom profilers, EcoMapper Autonomous Under Vehicle (EAUV), and acoustic doppler current profiler (ADCP). A hydrography survey deals with providing physical features such as understanding of underwater navigations, accurate positions, depictions of hills, etc., of waterbodies.

Both bathymetric and/or hydrographic surveys are useful in understanding the topography of water-bed such as locating any bed-rock outcrops, obstacles at bed level if any, and optimum locations for placing anchors and mooring for the floating platform. The bathymetric and hydrographic surveys that roughly take between 7 and 15 days to conduct, involve the use of precise instruments and methods. The survey gives information on the waterbed in the form of a contour map comprising details related to the depth of the waterbed with reference to datum level. The contour map, as shown in Figure 20, is a decisive factor in identifying the best places of anchoring and mooring, desilting requirements, etc.

---

---

![Figure 20](image)
This step is vital to judge the overall techno-commercial viability of the projects, and failure in conducting this properly could cause extensive damage to the FSPV plant as shown in Figure 21.

Typically instruments used for bathymetric/hydrographic surveys are shown in Figure 22. Soil testing is also an important step for deciding the type and design of anchoring that would be required. It provides information on soil composition of the banks and waterbody beds, etc. The soil test must be conducted as per IS: 2131-1963 and a testing report must contain information like – natural moisture content, bulk density, dry density, specific gravity, grain size distribution, and atterberg limits along with bore logs with SPT 'N' values.

Environmental and Social Impact Assessment detail ESIA

As highlighted in this report, the long-term impacts of deploying large-scale FSPV-based plants on the local environment are poorly known. Also, an FSPV plant includes components like floating platform, anchoring and mooring system, cables, inverters, etc. which are continuously exposed to water. Additionally, these waterbodies are often used for several social usages like fishing, farming, navigation, drinking, etc. and their characteristics vary widely and are site specific. Hence, it is imperative to conduct a detail ESIA for each site to assess the long term impact of deploying an FSPV on a particular waterbody and its suitability.

Project Design

Upon receiving the clearance from ESIA, designing of FSPV plants can begin. For the sake of simplicity, the entire project design needs the following three components –

- **Meteorological data** – Meteorological or met data are essential to understand the local resources pertaining to FSPV. The met data comprise solar radiation, wind direction, wind velocity, wave height and amplitude, humidity, ambient temperature, rainfall, etc.

- **Water quality information** – Water quality information is really crucial in selecting the material of anchoring and mooring system, floating platform, cables and understating the long-term effects it may cause on the life of FSPV plant components. Hence it is essential to have a thorough investigation on water quality of the waterbody while taking the sample from multiple points. A typical water quality report should contain information such as physical and chemical properties of water (PH, turbidity, salinity, dissolved oxygen (DO), total dissolved solids (TDS) level, temperature of water, etc., and must follow IS:10500 2012.

- **Simulation** – Simulation softwares like PVsyst, HelioScope, ANSYS, OrcaFlex, CFD, etc., can be used in designing the layout, angle of tilt, plot size, designing of anchoring and mooring lines, placement of inverters, plant capacity, balance of system (BOS), estimates of energy generations for the entire project life, etc.

The general steps for designing the FSPV plants are explained in Chart 18.

Angle of tilt

Dependencies of PV modules angle of tilt on the location of the plant and wind speeds are well known. In fact, the wind load plays a vital role in deciding the quantum of drag force being induced on the mounting structure. In case of FSPV plants, this is even of much importance, as an incorrect angle of tilt can induce higher drag forces causing severe damage to the entire plant structure. Typically, wind loads are measured as per the Indian Standards IS 875 (Part 3). The standard provides details of the wind speed for every Indian city. Based on multiple discussions with various expert groups, angle of tilt in case of FSPV projects can be kept as per the details given in Table 3.

Plot size

Generally, in ground-mounted solar PV plant, drag force is induced on the individual row of the panels and is irrespective of the plot size as shown in Figure 23. However, with respect to FSPV plants, since each row is connected to a single outer frame resembling a single plot, drag forces are induced on the entire plot as indicated in Figure 24. This makes the plot size, in the case of FSPV much more important in comparison to ground-mounted plants. To understand this let us take an example of a recent fire incident due to typhoon that happened in Japan’s 13.7MWp FSPV plant. The entire 13.7MWp plant, covering a total area of 137,326 m² was assembled in a large single outer frame. Due to its large plot size, the high drag force developed during the typhoon tore the plant from the middle section while anchoring lines remained intact, as depicted in Figure 25. Hence, in order to minimize the drag force, it is recommended to keep a single plot size small and symmetrical (not more than 3–4 MWp).

Calculation of drag forces

Once the angle of tilt and plot size are decided, the detailed analysis of drag forces over the entire plant must be investigated. CFD simulations are performed to calculate the value of drag force and its points of action over entire plot, as explained in the Figure 26.

![Figure 26: Drag forces on floating solar PV plant (a representational image)](image)

Source: TERI's analysis

Calculation of anchoring and mooring lines

After drag force and its points of action get simulated, forces induced on the anchoring and mooring lines can be calculated through softwares like OrcaFlex, ANSYS, etc. The results of the software are used in calculating the forces on individual points of the anchoring and mooring lines.

Response amplitude operator

A response amplitude operator (RAO) is a method that is used to find the floating structure's characteristic response created by wave action. The results obtained from this study help in choosing mooring wire ropes, which can sustain sufficient tensions in extreme conditions. The calculations of tensions (in kN) on different ropes are calculated in RAO.

Measuring end load and its comparison with the safe load

Once the tensions in different loads are identified, the next step is to calculate end loads on each of these points and this should be performed under permissible limits. Further, this calculation should be compared with safe load. The designs considered as safe if the end load is lesser than the safe load, otherwise the process has to be repeated till the value of end load becomes lesser than safe load.

Installation and Commissioning

In comparison to ground-based solar PV plants, FSPV plants are easy to install and may not require heavy civil construction in most cases. The entire process of installation and commissioning can be divided into three steps: a) site preparation and construction; b) installation and c) commissioning. As in any solar PV-based plant development, the first step is to prepare the site. This involves civil works for grading and leveling, excavating the foundation for mooring and anchoring, fabricating a dedicated launching platform for launching the floating platform into the water surface (this depends upon access to the water surface at the site), fabricating inverter housing, building embankment for foundation protection, etc. Installation begins after the initial site preparation is completed. It includes connecting the rows of floats to form a floating platform, mounting PV panels on the floating platform, connecting cables, inverters, transmission lines, etc. Since FSPV plants are installed on waterbodies and are often subjected to harsh environmental conditions like high humidity, high winds, etc., it is recommended that the solar PV panels, supporting structure and other balance of systems such as inverters, cables, etc., are chosen wisely. Some activities involved under installation and commissioning are likely to generate air and noise emissions. Such emissions and wastes generated could have an adverse impact on local bio-diversity. Therefore, it is essential to follow the recommendations provided in the ESIA report while adhering to the specific standards; some of them are also explained in the subsequent section.

Technical Specification and Standards

As discussed in this report, FSPV plants are deployed in waterbodies and often subjected to harsh environments. Hence it is important to consider relevant standards to ensure the quality of the FSPV plant components while being cautions of not degrading the quality of water as well as local bio-diversity. It is recommended to adhere to the following technical standards of the major components used in grid-connected FSPV-based plants –

Source: TERI’s compilation based on various tenders
Apart from the aforementioned technical standards, it is also important to consider the following points before deploying the FSPV-based plants:

» The material used for the floating platform must be UV stabilized (UV20) and should be manufactured from appropriate thermoplastic having good environmental stress crack resistance (ESCR) such that the floating platform can withstand a minimum operational period of 25 years without any discolouration. Also, materials used for floating platforms should be chemically resistant to acid, lye, petrol, mineral oil, and most importantly, should not contaminate the waterbody in any condition in its lifetime. Additionally, a floating platform, when deployed in waterbodies, containing raw water, should be designed in a manner such that it does not restrict the process of gas exchange across the air–water interface. This is why voids of appropriate size must be provided and should be made an integral part of floating platform design.

» The floating platform, module-mounting structure, and anchoring and mooring system must be designed while considering the worst-case scenario and must be able to withstand variation in ambient temperature in the range of +50°C to -10°C.

» In order to perform PV module cleaning and regular operation and maintenance, appropriate measures must be incorporated in the floating platform design.

» The floating platform must re-processable and recyclable at the end of its useful life.

» The anchoring and mooring system must be designed while considering the variation in water level and prevailing wind speed. It should also restrict any lateral movement of the plant as well as not cause any negative impact on local biodiversity of the waterbody.

» All cables and connectors used in FSPV plants are of solar grade and able to withstand harsh environmental conditions for 25 years.
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?
7. Challenges
As presented in this report, the FSPV sector is evolving very rapidly and will become an alternate popular way to generate solar energy very soon. However, very little know-how is available at the moment thus posing many challenges, which need to be addressed properly. Some of the key challenges associated with the FSPV are presented below.

**Technology Challenges**

**Unavailability of FSPV-specific standards / technical guidelines**

Since FSPV as a technology is still in its nascent stages, there are no specific standards/technical guidelines available at the moment. Unlike the ground-based solar PV projects, an FSPV project comprises floating platform and anchoring and mooring systems placed on top of the water surface. To ensure that these components can withstand harsh environmental conditions while retaining the quality over 25 years without causing any serious impact on local biodiversity it is important to formulate FSPV component-specific standards and technical guidelines for designing such plants.

**Unavailability of waterbody data**

There is no consolidated data of waterbodies with information on water surface area, waterlevel variations, local weather profiles, historical changes in the water surface, data on local biodiversity, etc. The waterbody data availability is a crucial parameter in estimating the actual potential and designing of FSPV. The current usage of waterbodies, types of waterbodies, and their ownership are also not defined.

**FSPV plant components safety and its long-term reliability**

An FSPV plant’s electrical and electronic components are constantly exposed to harsh environmental conditions such as high humidity, salinity of water, high wind speed, etc. Hence unlike ground-based solar PV, long-run risks of operation could be relatively high in case of FSPV plants. Additionally, components like floating platform, solar PV module, cables, etc., float upon the water surface, therefore, there might be a possibility that these components are prone to degradation, corrosion, and bio-fouling. Unexpected behaviour of these components not only has the potential to increase the O&M cost but also can cause serious safety issues jeopardizing the life of the personal operating the plant. However, till now, there is no such study that can highlight the long-term reliability of these components.

**Absence of local manufacturing**

Unlike the ground-based solar PV projects, floating platform and anchoring and mooring system constitute a major share after the solar PV modules, in the overall component of FSPV-based plants. Till now there are very few local manufacturers that have developed capabilities of providing floating platform and anchoring and mooring system. It is always beneficial to have local manufacturing facilities to bring down costs. Now since FSPV market in India is shaping up very fast, establishing local manufacturing market through appropriate policy support will not only help in bringing down costs but shall aid in developing the local market capabilities as well.

**Unavailability of bathymetry and other studies on water**

Both bathymetric and/or Hydrographic surveys are very useful in understanding the topography of waterbed. This step is vital to judge the overall techno-commercial viability of the projects and failure in conducting this properly might cause extensive damage to the FSPV plant. The accuracy of this survey depends upon the grid size chosen while conducting the survey. At the moment there are no guidelines or standards available that can provide any information on how to conduct this survey, which grid size to select, and so on.

**Environmental and Social Aspects**

Waterbodies are generally central to the living species’ settlements. In most cases, waterbodies are used for multiple
activities, such as fishing, livelihood generation, recreation, social activities, drinking, farming, aquatic life research, etc. Further, these waterbodies are rich in local aquatic flora and fauna. Long-term impacts of deploying largescale FSPV plants on local-biodiversity are poorly known, and there are no reported data/studies available that can provide proper information.

**Installation Challenges**

**Clearances for FSPV projects**

Presently, the guidelines/checklists are only available for ground-based solar PV projects and there is no information on what kinds of clearances are needed in the case of FSPV plants.

**Who owns the waterbody?**

Waterbodies are generally spread across large geographical area and often shared among multiple states/departments etc., making the process of taking clearance a complex task.

**Transportation of floating platform**

Often waterbodies are available in remote places and surrounded by mountainous range, forest areas, etc., making the accessibility difficult. Transportation of floats to remote places can add extra cost to the project. Also, establishing manufacturing units of floats near the project locations could pose some challenges and largely dependent on the project location and capacity of the plant.

**Operation and Maintenance Challenges**

Since FSPV plants are installed on the water surface rather than on land, it is relatively difficult to deal with O&M issues in such conditions. There are certain parts like anchoring and mooring that lie inside the water and are required to be inspected on a regular basis to ensure the plant’s stability. To tailor these, divers are needed, which adds extra cost to O&M. Also sudden fault, instances like of bird dropping, replacement of electrical parts, maintenance of cables and wires, etc., are complex things to handle and require special training to plant personnel.

**Quality**

The floating solar prices have fallen significantly during the past 2 years. However, FSPV projects are still more expensive than ground-mounted projects by 20–40%. While falling prices are the welcome trend, they could also pose challenges to project quality, which can further impact the local biodiversity. Therefore, there is a need to develop a protocol for measuring the long-term quality for deploying large-scale FSPV plants.
Floating Solar Photovoltaic (FSPV): A Third Pillar to Solar PV Sector?
8. Conclusion
With the rate of capacity additions growing almost 3.5 folds, and reaching 84.4 GW within the last 5–6 years, the journey of renewable energy capacity additions in India is being phenomenal so far. With scheme like Saubhagya, providing last mile connectivity, the regulatory structure in place is geared towards creating the demand for clean energy while making electricity affordable for all. With focus given to transforming the energy sector from fossil-based to zero-carbon globally, the Government of India is also playing its role in creating a favourable environment by introducing the relevant policy interventions that are needed. In fact being among the world’s fastest growing emerging economies and world’s second most populous country, make the country a key player in the global energy transitions. There are many ways to contribute in this transition, FSPV being one of them.

The report investigates the possible ways of utilizing the vast potential trapped in the country’s inland waterbodies (medium and large reservoirs) through installation of FSPV. FSPV looks promising to become a third pillar of the solar PV sector and its market share is likely to accelerate as the technology gets mature. It provides some inherent advantages like improvement in energy yield due to evaporative cooling effect because of vicinity to the water surface, alternate to land use (land neutrality), potential to use the existing power infrastructures, potential to save water evaporation loss, etc. However, FSPV is in nascent stage of its development in India and there are lots of questions particularly regarding its long-term impact on the local environment and bio-diversity which require answers before rushing into large scale deployment. Formulation of FSPV-specific standards and project development guidelines is the need of the hour and is of vital importance to reap the actual benefit of this technology without causing any negative impact on the local environment. In this initial stage, focus must be on the viability of FSPV as a technology and not on the tariff and hence monitoring of its performance and bringing it to public domain must be encouraged. This can be achieved via following the priorities presented in this report and sharing the learnings among the stakeholders.
